ABSTRACT

A transducer for a stringed instrument comprises a first uppermost coil and a second lowermost coil with the axes of the coils coincident. Permanent magnet pole pieces are arranged in the first coil and metallic non-magnetised pole pieces are arranged in
5 the second coil. Oppositely directed U-shaped shields each having a web and outwardly directed opposed flanges are arranged back to back and receive the coils to shield the coils from each other both magnetically and inductively.

FIG 1

TRANSDUCER FOR A STRINGED MUSICAL INSTRUMENT

THIS INVENTION relates to transducers or pickups for stringed musical instruments whose output is intended to be amplified. In particular, the invention provides an improved noise cancelling pickup.

5 The invention will be described by way of example with reference to the musical instrument to which the pickups are fitted as being electric guitars. It should be appreciated that this is by way of example only and that instruments other than guitars may also be fitted with pickups according to the invention.

Electric guitars typically have at least four strings which when vibrated produce
10 an output for amplification. The vibration of the strings is converted to electrical
signals by pickups. The frequency of the electrical signals produced by the pickups
corresponds to the frequency of vibration of the strings.

Pickups typically consist of a single bar magnet within a coil or a plurality of
rod magnets with a coil. the strings of the guitar are made of a magnetically
15 permeable material typically a ferromagnetic material and the magnetic lines of flux
developed by the permanent magnets are intercepted by the vibrating strings. This
causes variations in the field pattern and a varying current is caused to flow in the
coils. The frequency of the current corresponds to the frequency of vibration of the
strings.

20 The coils, as well as being influenced by vibration of the strings also are
subjected to noise. Noise is produced by lighting, electric motors and appliances and
other sources. This noise, or hum adversely affects the quality of the sound
reproduced by the pickups. The fundamental frequency of the electrical supply
voltage, typically 50Hz or 60Hz, is converted into an audible hum in the amplifying
25 equipment.

Many attempts have been made at ways of reducing or eliminating this noise but these attempts have introduced other undesirable effects.

Leo Fender in the 1940s was responsible for developing a single coil pickup. His design had excellent tonal characteristics but was particularly noise prone and 5 equated basically to a long antenna for extraneous noise such as 50Hz or 60Hz hum and buzz caused by mains wiring, transformers, electric motors, lighting and other electrical appliances.

United States patent 4442749 issued to DiMarzio discloses one such earlier attempt at reducing noise. DiMarzio disclosed an electrical pickup device for stringed 10 instruments. The device had a pair of superimposed coaxial bobbins each axially wound with a coil having its axis perpendicular to the strings of the instrument. An integral shield of magnetically permeable material was present and had a base disposed between the two bobbins perpendicular to the coil axis and two side walls extend upwardly and perpendicularly from the base to at least immediately below the 15 top face of the upper bobbin. A plurality of rod-like permanent magnets extended through the upper and lower coils. Thus, a plurality of rod magnets common to both coils were arranged within the coils.

The shield extended around three sides of the top coil. The shield was not particularly effective and allowed the magnetic field to influence the lower noise 20 cancelling coil and thus lowering the system inductance. The tonal structure of the pickup as a whole was adversely affected when the inductance was reduced below an acceptable level which DiMarzio remedied by overwinding the coils but this raised the impedance and destroyed the original tonal characteristics.

DiMarzio in a first device employed magnetic pole pieces common to both coils and this prohibits attaining a suitable overall inductance value because of inductance cancellation between the two coils.

DiMarzio in a second embodiment discloses a pickup having an upper coil
5 with a plurality of magnetic pole pieces arranged within it. A lower noise cancelling coil is also shown. A channel shaped member receives the upper coil. Although the channel member extends around the upper coil the coils are not effectively magnetically and inductively decoupled from one another. Both embodiments prohibit attaining a suitable system inductive value without overwinding because of
10 inductance cancellation between the coils. By doing this noise cancellation is achieved at the expense of tone quality because tonal characteristics are in the main dependent on inductance and impedance.

An attempt at noise cancellation in pickup design was also made by Seymour Duncan. His design used full length Alnico V magnets which extended vertically
15 through two coils. Like the DiMarzio design, the Duncan design also caused inductance and signal cancellation. Duncan did not employ any kind of magnetic barrier to separate the upper and lower coils. He also restored lost inductance by overwinding the coils.

A company known as EMG produced a pickup design known as (Strat
20 Vintage) SV. EMG employed full length magnets which extended through both an upper and a lower coil without a magnetic shield. Each coil was separately buffered into a two input differential operational amplifier but the system inductance was less than ideal 2.15 Henrys since the inductance of the top half coil was 0.8H. The lower coil was of similar inductance. They were not overwound.

There is no ready way of producing such a vintage sound with modern electric guitars while still providing for adequate noise cancellation.

SUMMARY OF THE INVENTION

It is an object of the present invention to provide an improved transducer or
5 pickup for stringed musical instruments which provides for effective noise or hum cancellation while not sacrificing tone quality.

According to one aspect of the invention, there is provided a transducer having a first coil, a second coil arranged with its axis coincident with the axis of the first coil and in use spaced below the first coil, a metallic shield made of magnetically
10 permeable material arranged between the coils, the shield having one or more outwardly directed walls with the wall or walls of the shield extending over sides of the coils, at least one permanent magnet pole piece associated with the first coil and at least one metallic magnetically permeable pole piece associated with the second coil, whereby the coils are inductively and magnetically decoupled from one another
15 by the shield.

According to another aspect of the invention, there is provided a transducer having a first coil, a second coil adjacent the first coil, a metallic shield made of magnetically permeable material arranged between the coils, the shield having one or more outwardly directed walls with the wall or walls of the shield extending over
20 sides of the coils and between the coils and at least one magnetic pole piece associated with the first and the second coil.

The upper and lower coils may be wound with the same or different gauge of wire. Preferably, each of the coils has between 1000 to 7000. More preferably, each coil has about 5000 turns. The coils need not have the same number of turns.

It is preferred that the coils be impedance matched at 50 or 60 Hz and tuned so that the inductance at 60 Hz of each coil is the same. This may be achieved by adopting a suitable wire gauge and number of turns for the coils and by the desired choice of the metallic pole pieces for the lower coil as discussed below.

- 5 As mentioned, there maybe a unitary metallic magnetically permeable pole piece associated within the lower coil. In an alternative construction, a plurality of metallic magnetically permeable pole pieces are present.

- The (single) or each (plural) metallic pole piece for the lower coil are preferably made of mild steel although other metals are not excluded. Where there are a 10 plurality of pole pieces, they may be full core height pieces extending through the lower coil.

- The lower coil is contained within the shield. The shield is made of a metallic magnetically permeable material. Typically, the shield is made from mild steel and may have a thickness of about 0.6mm. Respective non-metallic plates may be 15 arranged on both sides of the lower coil. The shield may be present as a tray having a base and a continuous upstanding wall. Alternatively, the shield may be U shaped having a base and two opposed upstanding side walls. The shield may be H shaped in transverse cross section and the lower coil may be received between the cross member of that section and the downwardly directed side walls.
- 20 The non-metallic plates may have a plurality of apertures for receiving the pole pieces located within the lower coil.

The upper coil is contained within the shield. The shield may be constructed in a similar fashion to the shield which receives the lower coil. As with the lower coil, respective non-metallic plates may be arranged on both sides of the upper coil. Of

course, if the shield is H shaped in transverse cross section the upper coil is received between the cross member of that section and the upwardly directed side walls.

The H shaped shield may be made as a unitary component or from several pieces.

- 5 As mentioned there may be a unitary permanent magnetic pole piece associated with the upper coil. Preferably, a plurality of permanent magnet pole pieces are associated with the upper coil.

- Permanent magnet pole pieces of a number commensurate with the number of strings of the instrument to which the transducer is fitted are preferably arranged
10 within the upper coil. Preferably, the non-metallic plates associated with the upper coil have apertures for receiving the magnetised pole pieces. Preferably, the pole pieces project through the apertures in the plate nearest to the instrument strings.

The magnetic pole pieces may be made from ALNICO II or ALNICO V or any other suitable magnetic material.

- 15 The two coils, because of the arrangement described are both magnetically and inductively isolated from one another. The upper coil is subjected to the influence of the movement of the strings and noise while the lower coil is subjected only to noise. Because of the close proximity of the coils to one another, they respond equally to the effects of noise. By connecting the coils together either in
20 parallel or series but out of phase, noise can be effectively cancelled from the signal.

In the embodiment where vintage sound is produced by the pickup at least one permanent magnet pole piece is located within each of the coils. The pole piece may be common to both coils although a separate pole piece may be employed for each coil. In one embodiment, each coil has a plurality of pole pieces. The plurality

of pole pieces may be common to both coils. Alternatively, each coil may have a separate set of pole pieces.

Where a plurality of pole pieces are present, the number corresponds to the number of strings on the instrument.

5 Non-metallic plates may be arranged adjacent to the ends of the pole pieces.

These plates may have holes for receiving the ends of the pole pieces.

BRIEF DESCRIPTION OF THE DRAWINGS

A particular preferred embodiment of the invention will now be described by way of example with reference to the drawings in which:

- 10 Figure 1 is an exploded perspective view of a transducer according to the invention;
- Figure 2 is an assembled perspective view of the transducer of Figure 1;

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Figure 1 shows a transducer 10 having a non-metallic nonconductive base plate 11. Plate 11 has a series of holes 12 for receiving mild steel non-magnetised pole pieces 13, 14, 15, 16, 17, 18. If desired, pole pieces 14, 15, 16 and 17 may be omitted from the transducer 10. Plate 19 is constructed of the same material as plate 11. A lower coil 20 extends around pieces 13 to 18 and is located between plates 11 and 19. Shield 21 has a web 22 and two opposed downwardly directed walls 23, 24. These walls extend over sides of the coil 20. Web 22 has rounded ends 25 (only one of which is visible in this view). Walls 23 and 24 terminate half way across the outermost pole pieces 13 and 18 although they may extend beyond them if desired.

An upper coil 30 is arranged between plates 31 and 32. These plates are constructed of the same material as plates 11 and 19. Plates 31 and 32 have holes 33 for receiving magnetic pole pieces 34, 35, 36, 37, 38, 39. A shield 40 having a web 41 and opposed walls 42, 43 together with shield 21 magnetically separate coil 5 30 from coil 20. Web 41 overlies and abuts against web 22. Walls 42, 43 extend upwardly and over sides of the coil 30. Web 41 has rounded ends 44 (only one of which is visible in this view). Walls 42, 43 terminate midway over the outermost pole pieces 34 and 39.

Figure 2 shows an assembled perspective view of the transducer 10. The 10 orientation assumed by strings 50, 51, 52, 53, 54, 55 relative to transducer 10 is shown. Coil 30 is shown closest to the strings while coil 20 is lowermost with the coils being coaxial with one another. The U shaped shields 21 and 40 effectively ensure that coil 20 is not subjected to the magnetic field of pole pieces 34, 35, 36, 37, 38, 39 and the magnetic field is directed towards the strings of the instrument to 15 which the transducer 10 is fitted.

Figure 3 is a transverse sectional view of the transducer 10 shown in Figure 2. The shields 21 and 40 are shown surrounding the respective coils on three sides. The walls 23 and 24 of shield 21 extend downwardly over sides of lower coil 20 while walls 42 and 43 of shield 40 extend upwardly over the sides of coil 30.
20 Magnetic pole piece 39 is held between plates 31 and 32 as indeed are the other pole pieces not visible in this view. Webs 22 and 41 separate the coils from one another. Base plate 11 and plate 19 receive metallic pole piece 18 between them as indeed is the other pole piece not visible in this view. Magnetic pole piece 39 extends a short distance beyond plate 31. So do the other magnetic pole pieces.

Figure 4 shows a transverse sectional view through the shields 21 and 40 with only the permanent magnet pole piece 39 and the metallic magnetically permeable pole piece 18 shown. These shields may be made as a unitary H shaped field.

- Figure 5 is a front elevational view of that part of the transducer shown in
- 5 Figure 4. The shield 40 has a web 41 and upwardly extending walls 42 (see Figure 4) and 43 which terminate halfway over outermost permanent magnet pole pieces 34, 39. Shield 21 has a web 22 and walls 23 (see Figure 4) and 24 which extend downwardly over the metallic magnetically permeable pole pieces 13 and 18. As mentioned previously, pole pieces 14, 15, 16 and 17 may be omitted.

- 10 Figure 6 shows an exploded perspective view of another transducer according to an embodiment of the invention. The transducer 60 has a base plate 61 constructed of a non-metallic material. Plate 61 has a slot 62 which receives a single mild steel core piece 63. A lower coil 64 locates about piece 63 and a plate 65 is positioned over the coil 64. A shield 66 extends over the coil 64 and has a web 67 with two opposed walls 68, 69. Walls 68, 69 extend over sides of the coil 64.

An upper coil 70 is present and rests upon lower plate 71. The coil 70 is received within shield 72. Shield 72 has a web 73 and opposed walls 74, 75 which extend over sides of the coil 70. A plate 76 extends over coil 70 and has a slot 77 for receiving permanent magnet pole piece 78.

- 20 In this embodiment, coil 70 has a single magnetic pole piece and a single metallic magnetically permeable pole piece is arranged within coil 64.

Figure 7 shows an alternative shield construction. Shield 80 is tray shaped and has a base 81 and a continuous upstanding wall 82. Pole pieces 83, 84, 85, 86, 87, 88 are shown and may either be permanent magnets or may be metallic

magnetically permeable depending upon whether shield 80 is used for an upper or lower coil.

- It is not necessary for the shields in a transducer to be both as shown in Figure 7 or both of the type shown in Figure 6. One of each may be used. Likewise, 5 a plurality of pole pieces may be present within one of the coils and a single pole piece may be present in the other of the coils.

It is preferred that the inductance and impedance of the two coils be matched by proper choice of number of turns, wire gauge and size of the pole piece or pieces within the coils.

- 10 Figure 8 shows a transducer 100 having a non-metallic nonconductive base plate 111. Plate 111 has a series of holes 112 for receiving magnetic pole pieces 134, 135, 136, 137, 138 and 139. Plate 119 is constructed of the same material as plate 111 and has holes 113 (only one of which is shown). A lower coil 120 extends around pieces 134 to 139 and is located between plates 111 and 119. Shield 121
15 has a web 122 and two opposed downwardly directed walls 123, 124. These walls extend over sides of the coil 120. Web 122 has rounded ends 125 (only one of which is visible in this view). Walls 123 and 124 terminate half way across the outermost pole pieces 134 and 139 although they may extend beyond them if desired.

- An upper coil 130 is arranged between plates 131 and 132. These plates are 20 constructed of the same material as plates 111 and 119. Plates 131 and 132 have holes 133 for receiving the magnetic pole pieces 134, 135, 136, 137, 138 & 139. A shield 140 having a web 141 and opposed walls 142, 143 together with shield 121 magnetically separate coil 130 from coil 120. Web 141 overlies and abuts against walls 142, 143 extend upwardly and over sides of the coil 130. Web 141
25 has rounded ends 144 (only one of which is visible in this view). Walls 142, 143

terminate midway over the outermost pole pieces 134 and 139. Plate 119 has a series of holes 113 through which the pole pieces 134 to 139 extend. Plate 132 has similar holes (not visible in this view).

Figure 9 shows an assembled perspective view of the transducer 110. The orientation assumed by strings 150, 151, 152, 153, 154, 155 relative to transducer 110 is shown. Coil 130 is shown closest to the strings while coil 120 is lowermost with the coils being coaxial with one another. The U shaped shields 121 and 140 divide the magnetic field into two sections, namely, a part within the coils and a part outside the coils. The outside field is uninterrupted from one end of the pole pieces to the other without inductive cancellation between the coils because the outside field has no effect on the inner field. The inner fields are confined to the coils in those fields. The coils are magnetically separate.

Figure 10 is a transverse sectional view of the transducer 110 shown in Figure 9. The shields 121 and 140 are shown surrounding the respective coils on three sides. The walls 123 and 124 of shield 121 extend downwardly over sides of lower coil 120 while walls 142 and 143 of shield 140 extend upwardly over the sides of coil 130.

Magnetic pole piece 137 is held between plates 131 and 111. Webs 122 and 141 separate the coils from one another. Magnetic pole piece 137 extends a short distance beyond plate 131. So do the other magnetic pole pieces.

Figure 11 shows a transverse sectional view through the shields 121 and 140 with only the permanent magnet pole piece 137 shown. These shields may be made as a unitary H shaped shield.

Figure 12 is a front elevational view of that part of the transducer shown in figure 11. The shield 140 has a web 141 and upwardly extending walls 142 (not

shown) and 143 which terminate halfway over the outermost permanent magnet pole pieces 134, 139. Shield 121 has a web 122 and walls 123 (not shown) and 124 which extend downwardly over the pole pieces 134 to 139 and halfway over pieces 134 and 139.

5 Figure 13 shows an exploded perspective view of another transducer according to an embodiment of the invention. The transducer 160 has a base plate 161 constructed of a non-metallic material. Plate 161 has a slot 162 which receives a permanent magnet pole piece 178. A lower coil 64 locates about piece 178 and a plate 165 is positioned over the coil 164. A shield 166 extends over the coil 164 and
10 has a web 167 with two opposed walls 168, 169 extend over sides of the coil 164.

An upper coil 170 is present and rests upon lower plate 171. The coil 170 is received within shield 172. Shield 172 has a web 173 and opposed walls 174, 175 which extend over sides of the coil 170. A plate 176 extends over coil 170 and has a slot 177 for receiving the permanent magnet pole piece 178. The plates 165 and 171
15 have slots 163 through which pole piece 178 extends. Although not visible in this view, shield 166 has a slot corresponding to slot 163 to allow pole piece 178 to extend between plates 176 and 161.

In this embodiment, a single magnet pole piece 178 is common to both coils 170 and 164.
20 Figure 14 is an exploded perspective view of a transducer 180. The transducer 180 has a non-metallic base plate 181 with a slot 182. Shield 183 has a web 184 and two downwardly directed side walls 185, 186 and is made of magnetically permeable material. Plate 187 is also made of non-metallic material. Permanent magnet pole piece 188 locates in slot 182 and against plate 187 and is
25 received within coil 189. The coil 189 is received within shield 183.

Shield 190 has a web 191 and side walls 192, 193 and is made of metal and is magnetically permeable. Plate 194 is made of non-metallic material and coil 195 is received between plate 194 and plate 196. Plate 196 is made of similar material to that from which plate 194 is made and has a slot 197 for receiving a permanent magnet pole piece 198.

In the embodiment of Figure 14, the pole pieces 188 and 198 are separated from one another by webs 184 and 191.

Figure 15 shows a construction similar to that of Figure 14. Base plate 200 is made of non-metallic material and has a plurality of holes 201 for receiving 10 permanent magnet pole pieces 202, 203, 204, 205, 206, 207. These pole pieces extend between plate 208 and plate 200. Plate 208 is constructed from the same material as plate 200 and has a plurality of holes 209 for receiving pole pieces 202 to 207.

Shield 210 has a web 211 and two side walls 212, 213. Shield 214 has a web 15 215 and two side walls 216, 217. Shields 210 and 214 are made from magnetically permeable material.

Coil 220 is located within shield 210 and pole pieces 202 to 207 are received within the coil.

Coil 225 is received within shield 214 and between plates 226 and 227. 20 These plates are made of a non metallic material and plate 227 has a plurality of holes 228. Permanent magnet pole pieces 229, 230, 231, 232, 233, 234 and received within apertures 228 and within the coil 225.

Figure 16 shows an assembled view of the transducer of Figure 15. Strings 237, 238, 239, 240, 241 and 242 extend over pole pieces 229 to 234.

Figure 17 shows a transverse sectional view through the transducer of Figure 15. This figure shows how pole piece 207 locates in apertures in plates 200 and 208 and extends through the lower coil. Likewise, pole piece 234 extends through plate 227 and beyond it and into plate 226.

5 Figures 18 and 19 show how the walls of the shields extend along the pole pieces 229 to 234 and 202 to 207 within the two coils of the transducer. These walls terminal partway along the outermost pole pieces.

The embodiments of the transducer of Figures 8 to 13 function to not only reduce noise of hum but have higher magnetic strength pole pieces within the coils 10 and the pole pieces are common to both coils. These embodiments allow a "vintage" sound to be achieved. The high magnetic strength achievable by these configurations, typically 1200 gauss when employing ALNICO V as the material from which the pole pieces are made cause the strings of the instrument to be attracted into contact with the frets of the instrument when the strings vibrate.

15 The embodiments of the transducer of Figures 14 to 19 allow two coils which are identical with respect to inductance, core material, wire gauge, number of turns and other features to be produced. This mirroring of the coils provides for substantially identical resonant peaks in each coil which allows an overall high Q to be obtained for the transducer. The magnetic polarity of the pole pieces, may be 20 opposed or non-opposed, thus, the adjacent poles may be south/south or south/north.

Both the embodiments of Figures 8 to 13 and 14 to 19 provide a pickup with a desirable high Q factor.

The Figure 8 to 13 embodiments have a high magnetic strength whereas the Figure 7 to 12 embodiments have a lower magnetic strength. The presence of the shields decouples the coils.

The Figure 14 to 19 embodiments allow high Q to be achieved with a lower
5 magnetic strength than that achieved with the Figure 8 to 13 embodiments.

WHAT IS CLAIMED IS:

1. A transducer having a first coil, a second coil arranged with its axis coincident with the axis of the first coil and in use spaced below the first coil, a metallic shield made of magnetically permeable material arranged between the coils, the shield
5 having an outwardly directed wall extending over a side of one of the first coil or the second coil for inductively and magnetically decoupling said coils from one another, at least one permanent magnet pole piece associated with the first coil and at least one metallic magnetically permeable pole piece associated with the second coil.
- 10 2. The transducer of claim 1, wherein said metallic shield has a respective outwardly directed wall at the opposite sides thereof with each outwardly directed wall extending over a respective side of one of the first coil or the second coil.
- 15 3. The transducer of claim 2, wherein said outwardly directed walls extend over a respective side of both said first coil and the second coil.
- 20 4. The transducer of claim 1, wherein said at least one permanent magnet pole piece is arranged within the upper coil and said at least one metallic magnetically permeable pole piece is arranged within the lower coil.
5. The transducer of claim 4 and having a plurality of permanent magnet pole pieces arranged within the upper coil and a plurality of metallic magnetically permeable pole pieces arranged within the lower coil.

6. The transducer of claim 5, wherein the shield is provided by two separate U-shaped shield members having opposed side walls and each said coil is received between opposed side walls of a respective said U-shaped shield member.
- 5 7. The transducer of claim 5, wherein each said coil is received between two spaced non-metallic plates.
8. The transducer of claim 7, wherein said non-metallic plates have apertures for receiving the or each said pole piece.
- 10
9. The transducer of claim 7, wherein the or each said permanent magnet pole piece within the first coil extends through and beyond the apertures in one said non-metallic plates.
- 15 10. The transducer of claim 1, wherein the coils have an equal number of turns.
11. The transducer of claim 1, wherein the coils have a different number of turns.
12. The transducer of claim 1, wherein the coils are both wound from wire having
20 the same gauge.
13. The transducer of claim 1, wherein the coils each have between 1000 to 7000 turns.
- 25 14. The transducer of claim 1, wherein the coils each have about 5000 turns.

15. The transducer of claim 1, wherein the shield has a web with rounded ends.
 16. The transducer of claim 5, wherein the permanent magnet pole pieces are
5 cylindrical in shape and are made from either ALNICO II or V.
 17. The transducer of claim 5, wherein the metallic magnetically permeable pole
pieces are cylindrical in shape and are made from mild steel.
- 10 18. An electric guitar pickup having:
a lower coil and an upper coil supported coaxially above the lower coil;
a continuous metallic shield made of magnetically permeable material
supported between the upper and lower coils;
a plurality of permanent magnet pole pieces extending through the core of the
15 upper coil, and
a plurality of magnetically permeable pole pieces extending through the core
of the lower coil.
19. An electric guitar pickup as claimed in claim 18, wherein said continuous
20 metallic shield includes at least one outwardly directed wall extending over a side of
one of the upper coil or said lower coil.
20. An electric guitar pickup as claimed in claim 18, wherein said upper and lower
coils are supported by respective dielectric supports which locate the pole pieces
25 within the respective cores of the coils.

21. An electric guitar pickup as claimed in claim 20, wherein the dielectric supports includes an apertured dielectric wall adjacent each end of each coil assembly, the apertures therein being aligned with the respective pole pieces which extend
5 therethrough for location and support.

22. An electric guitar pickup having:
a lower coil and an upper coil supported coaxially above the lower coil, the upper and lower coils having a different number of turns;
10 a continuous metallic shield made of magnetically permeable material supported between the upper and lower coils;
a plurality of permanent magnet pole pieces extending through the core of the upper coil, and
a plurality of magnetically permeable pole pieces extending through the core
15 of the lower coil.

23. A transducer comprising:
a first coil having a first axis;
a second coil having a second axis coincident with said first axis and spaced
20 below the first coil;
a magnetic shield made of magnetically permeable material arranged between the coils, said shield having at least one outwardly directed wall extending over a side of one of said first coil or said second coil;
at least one first permanent magnet pole piece associated with said first coil,
25 and

at least one magnetically permeable pole piece, separate from said first permanent magnet pole piece, associated with said second coil.

24. A transducer comprising:
- 5 a first coil having a first axis;
- a second coil having a second axis coincident with said first axis and spaced below the first coil and being wound with a different number of turns than the first coil
- a magnetic shield made of magnetically permeable material arranged between the coils, said shield having at least one outwardly directed wall extending over a
- 10 side of one of said first coil or said second coil;
- at least one first permanent magnet pole piece associated with said first coil, and
- at least one magnetically permeable pole piece, separate from said first permanent magnet pole piece, associated with said second coil.
- 15
25. An electric guitar pickup having a first coil, a second coil arranged with its axis coincident with the axis of the first coil and in use spaced below the first coil, a metallic shielding wall or walls made of magnetically permeable material and arranged between the coils for inductively and magnetically decoupling said coils
- 20 from one another, at least one permanent magnet pole piece associated with the first coil and at least one metallic magnetically permeable pole piece associated with the second coil.

26. An electric guitar pickup as claimed in claim 25 and having a plurality of permanent magnet pole pieces arranged within the upper coil and a plurality of metallic magnetically permeable pole pieces arranged within the lower coil.
- 5 27. An electric guitar pickup as claimed in claim 26 and said first and second coils being wound with a different number of turns.
28. An electric guitar pickup having:
a lower coil and an upper coil supported coaxially above the lower coil;
10 a magnet pole piece positioned in the upper coil, and
a magnetically permeable pole piece positioned in the lower coil.
29. The electric guitar pickup of claim 28 wherein:
said magnetic pole piece is a plurality of magnetic pole pieces.
15
30. The electric guitar pickup of claim 28 wherein:
said magnetically permeable pole pieces is a plurality of magnetically permeable pole pieces.
- 20 31. An electric guitar pickup having:
a first coil;
a second coil;
a magnet pole piece positioned in the first coil, and
a magnetically permeable pole piece positioned in the second coil wherein
25 said first coil and said second coil have a different number of turns.

32. An electric guitar pickup having:
- a first coil;
- second coil;
- 5 a magnet pole piece positioned in the first coil, and
- a magnetically permeable pole piece positioned in the second coil
- wherein said first coil and said second coil have a different gauge wire

DATED THIS Ninth DAY OF March 2000.
